

Git Commands Reference

git init

Initializes a new Git repository in the current directory.

git clone [repository URL]

Makes a copy of an existing Git repository to your local machine.

git add [file/folder]

Adds changes to the staging area before committing them.

git commit -m "message"

Commits changes to the local repository with a descriptive message.

git status

Shows the current status of the repository, including any changes that have been made.

git log

Displays a log of all commits made to the repository.

git branch

Lists all branches in the repository.

git checkout [branch name]

Switches to a different branch in the repository.

git merge [branch name]

Merges changes from one branch into another.

git pull

Fetches changes from the remote repository and merges them into the local repository.

git push

Uploads changes from the local repository to the remote repository.

git remote add [name] [URL]

Adds a new remote repository to the local repository.

git remote -v

Lists all remote repositories connected to the local repository.

git diff

Shows the differences between the local repository and the staging area or working directory.

git reset

Resets changes made to the repository, removing them from the staging area.

git rm [file]

Removes a file from the repository.

git mv [old file name] [new file name]

Renames a file in the repository.

git tag [tag name]

Creates a new tag for a specific commit.

git fetch

Downloads changes from the remote repository without merging them into the local repository.

git stash

Saves changes made to the working directory for later use.

git pull --rebase

Fetches changes from the remote repository and rebases them onto the local branch.

git revert [commit]

Reverts changes made in a specific commit and creates a new commit to undo them.

git show [commit]

Shows details about a specific commit, including its message and changes.

git branch -d [branch name]

Deletes a branch from the repository.

git branch -m [old branch name] [new branch name]

Renames a branch in the repository.

git push -u [remote name] [branch name]

Sets the default upstream branch for a local branch.

git checkout -b [new branch name]

Creates a new branch and switches to it.

git log --oneline

Displays a short log of all commits made to the repository.

git log --graph

Displays a graphical representation of the commit history.

git merge --abort

Aborts a merge that is currently in progress.

git commit --amend

Adds changes to the previous commit instead of creating a new one.

git config --global user.name "[name]"

Sets the name associated with Git commits.

git config --global user.email "[email address]"

Sets the email associated with Git commits.

git config --global color.ui true

Enables colored output in Git commands.

git stash pop

Applies the most recent stash to the working directory.

git clean

Removes untracked files from the working directory.

git remote rm [remote name]

Removes a remote repository from the local repository.

git diff HEAD

Shows the differences between the local repository and the last commit.

git reset --hard

Resets all changes made to the repository, removing them from the working directory.

git reset --soft [commit]

Resets the repository to a specific commit but keeps the changes in the staging area.

git pull --rebase origin [branch name]

Fetches changes from the remote repository and rebases them onto the local branch.

git config --list

Lists all Git configuration settings.

git show-branch

Displays a graphical representation of the relationship between different branches.
